

# Unit 2: First Order Linear Differential Equations — Practice Problems and Solutions

Prepared by Staples Education

*Review Guide of Graded Problems with Complete Step-by-Step Solutions*

---

## Part II — Review Guide: Practice Problems

Work the following ten problems in order; they are graded from direct separation through linear factors, initial value problems, the homogeneous substitution, and a full physical model. Solutions follow in Part III.

1. Solve  $\frac{dy}{dx} = \frac{x}{y}$  by separation of variables.
  2. Solve  $\frac{dy}{dx} = e^{x-y}$ .
  3. Solve  $\frac{dy}{dx} = y \cos x$ , and identify any solution that is lost when you divide by  $y$ .
  4. Solve the linear equation  $\frac{dy}{dx} + 3y = 6$  using an integrating factor.
  5. Solve  $x \frac{dy}{dx} + y = x^2$  by first writing it in standard linear form.
  6. Solve  $\frac{dy}{dx} + \frac{2}{x}y = x$ .
  7. Solve the initial value problem  $\frac{dy}{dx} + 2y = 4$  with  $y(0) = 1$ .
  8. Solve the homogeneous equation  $\frac{dy}{dx} = \frac{x+y}{x}$  using the substitution  $y = vx$ .
  9. Solve the homogeneous equation  $\frac{dy}{dx} = \frac{x^2 + y^2}{xy}$  using  $y = vx$ .
  10. **(Application)** An object at  $100^\circ$  is placed in a room held at  $20^\circ$ . After 10 minutes its temperature is  $60^\circ$ . Find the temperature function  $T(t)$  and determine how long it takes the object to reach  $30^\circ$ .

## Part III — Complete Solutions

**Solution 1.** Separate, then integrate.

$$\begin{aligned}y \, dy &= x \, dx \\ \frac{y^2}{2} &= \frac{x^2}{2} + C_1 \\ y^2 &= x^2 + C \quad (\text{general solution}).\end{aligned}$$

**Solution 2.** Split the exponential as  $e^{x-y} = e^x e^{-y}$ , then separate.

$$\begin{aligned}e^y \, dy &= e^x \, dx \\ e^y &= e^x + C \\ y &= \ln(e^x + C).\end{aligned}$$

**Solution 3.** Separate (assuming  $y \neq 0$ ), integrate, and exponentiate.

$$\begin{aligned}\frac{1}{y} \, dy &= \cos x \, dx \\ \ln |y| &= \sin x + C \\ y &= C e^{\sin x}.\end{aligned}$$

Dividing by  $y$  assumed  $y \neq 0$ , so it dropped the equilibrium solution  $y = 0$  — which is recovered as the special case  $C = 0$ .

**Solution 4.** Here  $P = 3$ , so the integrating factor is  $\mu = e^{\int 3 \, dx} = e^{3x}$ . Multiply through:

$$\begin{aligned}\frac{d}{dx} [e^{3x} y] &= 6 e^{3x} \\ e^{3x} y &= \int 6 e^{3x} \, dx = 2 e^{3x} + C \\ y &= 2 + C e^{-3x}.\end{aligned}$$

**Solution 5.** Divide by  $x$  to reach standard form:

$$\frac{dy}{dx} + \frac{1}{x} y = x, \quad \mu = e^{\int (1/x) \, dx} = e^{\ln |x|} = x.$$

Multiply through and integrate:

$$\begin{aligned}\frac{d}{dx} [xy] &= x \cdot x = x^2 \\ xy &= \frac{x^3}{3} + C \\ y &= \frac{x^2}{3} + \frac{C}{x}.\end{aligned}$$

**Solution 6.** With  $P = \frac{2}{x}$ , integrate the coefficient and exponentiate:

$$\mu = e^{\int (2/x) dx} = e^{2 \ln |x|} = x^2.$$

Multiply through and integrate:

$$\frac{d}{dx}[x^2 y] = x^2 \cdot x = x^3$$

$$x^2 y = \frac{x^4}{4} + C$$

$$y = \frac{x^2}{4} + \frac{C}{x^2}.$$

**Solution 7.** The integrating factor is  $\mu = e^{\int 2 dx} = e^{2x}$ . Multiply through and integrate:

$$\frac{d}{dx}[e^{2x} y] = 4 e^{2x}$$

$$e^{2x} y = 2 e^{2x} + C$$

$$y = 2 + C e^{-2x}.$$

Apply the initial condition  $y(0) = 1$ :

$$1 = 2 + C \implies C = -1$$

$$y = 2 - e^{-2x}.$$

**Solution 8.** Rewrite as  $\frac{dy}{dx} = 1 + \frac{y}{x}$  and substitute  $y = vx$ , so  $\frac{dy}{dx} = v + x \frac{dv}{dx}$ :

$$v + x \frac{dv}{dx} = 1 + v$$

$$x \frac{dv}{dx} = 1 \implies dv = \frac{1}{x} dx$$

$$v = \ln |x| + C.$$

Back-substitute  $v = \frac{y}{x}$ :

$$y = x \ln |x| + Cx.$$

**Solution 9.** Substitute  $y = vx$ . The right side becomes

$$\frac{x^2 + v^2 x^2}{x \cdot vx} = \frac{1 + v^2}{v}.$$

With  $\frac{dy}{dx} = v + x \frac{dv}{dx}$ ,

$$v + x \frac{dv}{dx} = \frac{1 + v^2}{v} = \frac{1}{v} + v$$

$$x \frac{dv}{dx} = \frac{1}{v} \implies v dv = \frac{1}{x} dx$$

$$\frac{v^2}{2} = \ln |x| + C_1 \implies v^2 = 2 \ln |x| + C.$$

Back-substitute  $v = \frac{y}{x}$ :

$$\frac{y^2}{x^2} = 2 \ln |x| + C \implies y^2 = x^2 (2 \ln |x| + C).$$

**Solution 10.** Newton's law of cooling with surrounding temperature  $T_s = 20$  and initial temperature  $T_0 = 100$  gives

$$T(t) = 20 + (100 - 20) e^{-kt} = 20 + 80 e^{-kt}.$$

Use the reading  $T(10) = 60$  to find  $k$ :

$$60 = 20 + 80 e^{-10k} \implies 80 e^{-10k} = 40$$

$$e^{-10k} = \frac{1}{2} \implies -10k = -\ln 2 \implies k = \frac{\ln 2}{10}.$$

Hence the temperature function is

$$T(t) = 20 + 80 e^{-(\ln 2/10)t} = 20 + 80 \left(\frac{1}{2}\right)^{t/10}.$$

To reach  $30^\circ$ , solve  $T(t) = 30$ :

$$30 = 20 + 80 e^{-kt} \implies 80 e^{-kt} = 10 \implies e^{-kt} = \frac{1}{8}$$

$$-kt = -\ln 8 = -3 \ln 2 \implies t = \frac{3 \ln 2}{k} = \frac{3 \ln 2}{\ln 2/10} = 30 \text{ minutes}.$$

### Unit 2 Key Takeaway

Every method in this unit reduces to a single move — rewrite the equation into a form you can integrate. **Separation of variables** splits a factored rate law; the **integrating factor**  $\mu = e^{\int P dx}$  collapses a linear left side into one derivative; and the **substitution**  $y = vx$  turns a homogeneous equation separable. Read the structure first, and the technique always follows.
